

1 Apache::FakeRequest - fake request object for debugging

1.1 Synopsis

```
use Apache::FakeRequest;  
my $request = Apache::FakeRequest->new(method_name => 'value', ...);
```

1.2 Description

`Apache::FakeRequest` is used to set up an empty Apache request object that can be used for debugging.

The `Apache::FakeRequest` methods just set internal variables of the same name as the method and return the value of the internal variables. Initial values for methods can be specified when the object is created. The `print` method prints to `STDOUT`.

Subroutines for Apache constants are also defined so that using `Apache::Constants` while debugging works, although the values of the constants are hard-coded rather than extracted from the Apache source code.

```
#!/usr/bin/perl  
  
use Apache::FakeRequest ();  
use mymodule ();  
  
my $request = Apache::FakeRequest->new('get_remote_host'=>'foobar.com');  
mymodule::handler($request);
```

1.3 Authors

Doug MacEachern, with contributions from Andrew Ford <A.Ford@ford-mason.co.uk>.
